**DESCRIPTION**

The LTC®4314 is a hot-swappable 4-channel 2-wire bus multiplexer that allows one upstream bus to connect to any combination of downstream busses or channels. An individual enable pin controls each connection. The LTC4314 provides bidirectional buffering, keeping the upstream bus capacitance isolated from the downstream bus capacitances. The high noise margin allows the LTC4314 to be interoperable with I²C devices that drive a high VOL (> 0.4V). The LTC4314 supports level translation between 1.5V, 1.8V, 2.5V, 3.3V and 5V busses. The hot-swappable nature of the LTC4314 allows I/O card insertion into, and removal from, a live backplane without corruption of the data and clock busses.

If both data and clock are not simultaneously high at least once in 45ms and DISCEN is high, a FAULT signal is generated indicating a stuck bus low condition, the input is disconnected from all enabled output channels, and up to 16 clocks are generated on the enabled downstream busses. A three state ACC pin enables input and output side rise time accelerators of varying strengths and sets the VIL,RISING voltage.

**FEATURES**

- 1:4 Multiplexer/Switch for 2-Wire Bus
- Bidirectional Buffer for SDA and SCL Lines
- High Noise Margin with VIL = 0.3\*VCC
- ENABLE Pins Connect SDA and SCL Lines
- Selectable Rise Time Accelerator Current and Activation Voltage
- Level Shift 1.5V, 1.8V, 2.5V, 3.3V and 5V Busses
- Prevents SDA and SCL Corruption During Live Board Insertion and Removal from Backplane
- Stuck Bus Disconnect and Recovery
- Compatible with I²C, I²C Fast Mode and SMBus
- ±4kV Human Body Model (HBM) ESD Ruggedness
- 20-Lead SSOP and 3mm × 4mm QFN Packages

**APPLICATIONS**

- Telecommunications Systems Including ATCA
- Address Expansion
- Level Translator
- Capacitance Buffers/Bus Extender
- Live Board Insertion
- PMBus

**TYPICAL APPLICATION**

</tr>
</tbody>
</table>

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** All currents into pins are positive and all voltages are referenced to GND unless otherwise indicated.

**Note 3:** SDAIN, SCLIN pulled low.

**Note 4:** $V_{MIN}$ = minimum of $V_{CC}$ and $V_{CC2}$ if $V_{CC2} > 2.25V$ else $V_{MIN} = V_{CC}$.

**Note 5:** $V_{IL}$ is tested for the following ($V_{CC}$, $V_{CC2}$) combinations: (2.9V, 5.5V), (5.5V, 2.25V), (3.3V, 3.3V) and (5V, 0V).

**Note 6:** Guaranteed by design and not tested.

**Note 7:** Measured in a special DC mode with $V_{SDA,SCL} = V_{RTA\_TH} + 1V$. The transient $I_{RTA}$ seen during rising edges when ACC is low will depend on the bus loading condition and the slew rate of the bus. The LTC4314's internal slew rate control circuitry limits the maximum bus rise rate to 75V/μs by controlling the transient $I_{RTA}$.

PIN FUNCTIONS

ACC: Three-State Acceleration and Buffer Mode Selector. This pin controls the turn on voltage of the rise time accelerators and their current strength on both the input and output sides. It also controls the turn-off voltage of the buffers. See Table 1 in the Applications Information section.

DISCEN: Disconnect Stuck Bus Enable Input. When this pin is high, stuck busses are automatically disconnected and FAULT is pulled low after a timeout period of 45ms. Up to sixteen clock pulses are subsequently applied to the stuck output channels. When DISCEN is low, stuck busses are neither disconnected nor clocked but FAULT is pulled low. Connect to GND if unused.

ENABLE1-ENABLE4: Connection Enable Inputs. These input pins enable or disable the corresponding output channel. Driving an ENABLE pin low isolates SDAIN and SCLIN from the corresponding SDAOUT and SCLOUT. Only enable and disable a channel when all busses are idle. During bus stuck low fault condition, a falling edge on all ENABLE pins followed by a rising edge on one or more ENABLE pins forces a connection from SDAIN to the selected SDAOUT and SCLIN to the selected SCLOUT. Connect to GND if unused.

Exposed Pad (QFN Package Only): Exposed pad may be left open or connected to device GND.

FAULT: Stuck Bus Fault Output. This open drain N-channel MOSFET output pulls low if a simultaneous high on the enabled SCLOUT and SDAOUT channels does not occur in 45ms. In normal operation FAULT is high. Connect a pull up resistor, typically 10k, from this pin to the bus pull-up supply. Leave open or tie to GND if unused.

GND: Device Ground.

SCLIN: Upstream Serial Bus Clock Input/Output. Connect this pin to the SCL line on the upstream bus. Connect an external pull-up resistor or current source between this pin and the bus supply. Do not leave open.

SCLOUT1-SCLOUT4: Downstream Serial Bus Clock Input/Output Channels 1-4. Connect pins SCLOUT1-SCLOUT4 to the SCL lines on the downstream channels 1-4, respectively. When in use, an external pull-up resistor or current source is required between the pin and the corresponding bus supply. Leave open or tie to GND and connect the corresponding ENABLE pin to GND if unused.

SDAIN: Upstream Serial Bus Data Input/Output. Connect this pin to the SDA line on the upstream bus. Connect an external pull-up resistor or current source between this pin and the bus supply. Do not leave open.

SDAOUT1-SDAOUT4: Downstream Serial Bus Data Input/Output Channels 1-4. Connect pins SDAOUT1-SDAOUT4 to the SDA lines on downstream channels 1-4, respectively. When in use, an external pull-up resistor or current source is required between the pin and the corresponding bus supply. Leave open or tie to GND and connect the corresponding ENABLE pin to GND if unused.

VCC: Power Supply Voltage. Power this pin from a supply between 2.9V and 5.5V. Bypass with at least 0.01μF to GND.

VCC2: Output Side Rise Time Accelerator (RTA) Power Supply Voltage. When powering VCC2, use a supply voltage ranging from 2.25V to 5.5V and bypass with at least 0.01μF to GND. If the downstream busses are powered from multiple supply voltages, power VCC2 from the lowest supply voltage. Output side RTAs are active if VCC2 ≥ 2.25V and ACC is low or open. Grounding VCC2 disables output side RTAs.

The Block Diagram shows the major functional blocks of the LTC4314. The LTC4314 is a 1:4 multiplexer with capacitance buffering for I^2C signals. Capacitance buffering is achieved by use of back to back buffers on the clock and data channels which isolate the SDAIN and SCLIN capacitances from the SDAOUT and SCLOUT capacitances respectively. All SDA and SCL pins are fully bidirectional. The high noise margin allows the LTC4314 to operate with I^2C devices that drive a non-compliant high V\text{OL}. Multiplexing is done using N-channel MOSFETs that are controlled by dedicated ENABLE pins. When enabled, rise time accelerator pull-up currents I_{RTA} turn on during rising edges to reduce system rise time. In a typical application the input side bus is pulled up to VCC and the output side busses are pulled up to V\text{CC2} although these are not requirements. V\text{CC} is the primary power supply to the LTC4314. V\text{CC} and V\text{CC2} serve as the input and output side rise time accelerator supplies respectively. Grounding V\text{CC2} disables the output side rise time accelerators. The multiplexer N-channel MOSFET gates of the enabled channels are driven to V\text{CC2} if V\text{CC2} is > 1.8V, otherwise they are driven to V\text{CC}.

When the LTC4314 first receives power on its V\text{CC} pin, it starts out in an undervoltage lockout mode (UVLO) until 110μs after V\text{CC} exceeds 2.3V. During this time, the buffers and rise time accelerators are disabled, the multiplexer gates are off and the LTC4314 ignores transitions on the clock and data pins independent of the state of the ENABLE pins. V\text{CC2} transitions from a high to a low or vice-versa across a 1.8V threshold also cause the LTC4314 to disable the buffers, rise time accelerators and transmission gates and to ignore the clock and data pins until 110μs after that transition. Assuming that the LTC4314 is not in UVLO mode, when one or more ENABLEs is asserted, the LTC4314 activates the connection circuitry between the SDAIN, SCLIN inputs and selected output channels. The input rise time accelerators and the output rise time accelerators of the selected channels are also enabled at this time. When a SDA,SCL input pin or output pin on an enabled output channel is driven below the V_{IL,FALLING} level of 0.33\times V_{\text{MIN}}, the buffers are turned on and the logic low level is propagated though the LTC4314 to the other side. For V\text{CC2} > 1.8V, V_{\text{MIN}} is the lower of the V\text{CC} and V\text{CC2} voltages. For V\text{CC2} < 1.8V, V_{\text{MIN}} is the V\text{CC} voltage.

The LTC4314 is designed to sink a minimum total bus current I_{OL} of 4mA while holding a V_{OL} of 0.4V. If multiple output channels are enabled, the bus current of all enabled channels needs to be summed to get the total bus current. See the Typical Performance Characteristics curves for I_{OL} as a function of temperature.

A high occurs when all devices on the input and output sides release high. Once the bus voltages rise above the V_{IL,RISING} level, which is determined by the state of the ACC pin, the buffers are turned off. The rise time accelerators are turned on at a slightly higher voltage. The rise time accelerators accelerate the rising edges of the SDA,SCL inputs and selected outputs up to voltages of 0.9\times V\text{CC} and 0.8\times V\text{CC2} respectively, provided that the busses on their own are rising at a minimum rate of 0.2V/μs as determined by the slew rate detectors. ACC is a 3-state input that controls V_{IL,RISING}, the rise time accelerator turn-on voltage and the rise time accelerator pull-up strength.

The LTC4314 detects a bus stuck low (fault) condition when both clock and data busses are not simultaneously high at least once in 45ms. The voltage monitoring for a stuck low condition is done on the common internal node of the clock and data outputs. Hence a stuck low condition is detected only if it occurs on an enabled output channel. When a stuck bus occurs, the LTC4314 asserts the FAULT flag. If DISCEN is tied high, the LTC4314 also disconnects the input and output sides. After waiting at least 40μs, it generates up to sixteen 5.5kHz clock pulses on the enabled SCLOUT pins and a stop bit to attempt to free the stuck bus. If the bus recovers high before 16 clocks are issued, the LTC4314 ceases issuing clocks and generates a stop bit. If DISCEN is tied low, a stuck bus event only causes FAULT flag assertion. Disconnection of the input and output sides and clock generation do not occur. Once the stuck bus recovers and the fault has been cleared, in order for a connection to be established between the input and output sides, all ENABLE pins need to be driven low followed by the assertion high of the desired ENABLE pins. When powering into a stuck low condition, the LTC4314 upon exiting UVLO will connect the input and output sides for 45ms until a stuck bus timeout event is detected.
APPLICATIONS INFORMATION

The LTC4314 is a 1:4 pin selectable I2C multiplexer that provides a high noise margin, capacitance buffering and level translation capability on its clock and data pins. Rise time accelerators accelerate rising edges to enable operation at high frequencies with heavy loads. These features are illustrated in the following subsections.

Rise Time Accelerators and DC Hold-Off Voltage

Once the LTC4314 has exited UVLO and a connection has been established between the SDA and SCL inputs and outputs, the rise time accelerators on both the input and output sides of the SDA and SCL busses are activated based on the state of the \( \text{ACC} \) pin and the \( V_{CC2} \) supply voltage. During positive bus transitions of at least 0.2V/\( \mu \)s, the rise time accelerators provide pull-up currents to reduce rise time. Enabling the rise time accelerators allows users to choose larger bus pull-up resistors, reducing power consumption and improving logic low noise margins, to design with bus capacitances outside of the I2C specification, or switch at a higher clock frequency. The \( \text{ACC} \) pin sets the turn-off threshold voltage for the buffers, the turn-on voltage for the rise time accelerators, and the rise time accelerator pull-up current strength. The \( \text{ACC} \) functionality is shown in Table 1. Set \( \text{ACC} \) open or high when a high noise margin is required, such as when the LTC4314 is used in a system having I2C devices with \( V_{OL} > 0.4 \)V. The \( \text{ACC} \) pin has a resistive divider between \( V_{CC} \) and ground to set its voltage to 0.5•\( V_{CC} \) if left open. In the current source accelerator mode, the LTC4314 provides a 3mA constant current source pull-up.

In the strong mode, the LTC4314 sources pull-up current to make the bus rise at 75V/\( \mu \)s (typical). The strong mode current is therefore directly proportional to the bus capacitance. The LTC4314 is capable of sourcing a maximum of 45mA of current in the strong mode. The effect of the rise time accelerator strength is shown in the SDA waveforms in Figures 1 and 2 for identical bus loads for a single enabled output channel. The rise time accelerator supplies 3mA and 10mA of pull-up current (\( I_{RTA} \)) respectively in the current source and strong modes for the bus conditions shown in Figures 1 and 2. The rise time accelerator turn-on voltage is also lower in the strong mode than in the current source mode. For identical bus loading conditions, the busses return high faster in Figure 1 compared to Figure 2 because of both the higher \( I_{RTA} \) and the lower turn-on voltage of the rise time accelerator. In each figure, note that the input and output rising waveforms are nearly coincident due to the input and output busses having nearly identical bus current and capacitance.
If VCC2 is tied low, the output side rise time accelerators are disabled independent of the state of the ACC pin. Using a combination of the ACC pin and the VCC2 voltage allows the user independent control of the input and output side rise time accelerators. The rise time accelerators are also internally disabled during power-up and VCC2 transitions as described in the Operation section, as well as during automatic clocking and stop bit generation for a bus stuck low recovery event.

The rise time accelerators when activated pull the bus up to 0.9VCC on the input side of the SDA and SCL lines. On the output side the SDAOUT and SCLOUT lines are pulled up by the rise time accelerators to 0.8VCC2. For VCC2 voltages approaching 2.3V, acceleration of the bus may not be seen all the way to 0.8VCC2 due to the threshold voltage of the NFET pass device.

Supply Voltage Considerations in Level Translation Applications

Care must be taken to ensure that the bus supply voltages on the input and output sides are greater than 0.9VCC and 0.8VCC2 respectively to ensure that the bus is not driven above the bus supplies by the rise time accelerators. This is usually accomplished in a level shifting application by tying VCC to the input bus supply and VCC2 to the lowest bus supply on the output side as shown in Figure 3.

If VCC2 is grounded, the multiplexer pass gates are powered from VCC. In this case the minimum output bus supply of the enabled channels should be greater than or equal to VCC to prevent cross-conduction between the enabled output channels. This is shown in Figure 4. Grounding VCC2 as shown in Figure 4 disables the output side rise time accelerators independent of the state of the ACC pin. The input rise time accelerators in this configuration continue to be controlled by the ACC pin and can be enabled independently. In Figure 4, ACC is left open to obtain a high VIL and a 3mA rise time accelerator current on the input side.

Pull-Up Resistor Value Selection

To guarantee that the rise time accelerators are activated during a rising edge, the bus must rise on its own with a positive slew rate of at least 0.4V/μs. To achieve this, choose a maximum RBUS using equation 1:

\[ R_{BUS} (\Omega) \leq \frac{\left( V_{DD, BUS(MIN)} - V_{RTA(TH)} \right)}{0.4V/\mu s \cdot C_{BUS}} \]  

(1)

RBUS is the bus pull-up resistor, VDD, BUS(MIN) the minimum bus pull-up supply voltage, VRTA(TH) the voltage at which the rise time accelerator turns on, which is a function of ACC, and CBUS the equivalent bus capacitance.

**Figure 3. Connection of the LTC4314 in a Level Shift Application. VCC2 is Less than or Equal to the Minimum Bus Supply Voltage on the Output Side**
R\textsubscript{BUS} values on each output channel must also be chosen to ensure that when all the required output channels are enabled, the total bus current is ≤4mA. The bus current in each output channel can be 4mA if only one channel is enabled at any given time. The R\textsubscript{BUS} value on the input must also be chosen to limit the bus current to be ≤4mA. The bus current for a single bus is determined by equation 2:

\[
I_{\text{BUS}}(A) = \frac{V_{\text{DD,BUS}} - 0.4V}{R_{\text{BUS}}}.
\] (2)

\textbf{Input to Output Offset Voltage and Propagation Delay}

The LTC4314 introduces both an offset as well as a propagation delay for falling edges between the input and output. When a logic low voltage ≥ 200mV is driven on any of the LTC4314’s data or clock pins, the LTC4314 regulates the voltage on the opposite side to a slightly higher value. When SCLIN or SDAIN is driven to a logic low voltage, SCLOUT or SDAOUT is driven to a slightly higher voltage, as directed by equation 3 which uses SDA as an example:

\[
V_{\text{SDAOUT}}(V) = V_{\text{SDAIN}} + 45mV + (10\Omega + R_{\text{MUX}}) \cdot \frac{V_{\text{DD,BUS}}}{R_{\text{BUS}}}.
\] (3)

V\text{DD,BUS} is the output bus voltage, R\text{BUS} is the output bus pull-up resistance and R\text{MUX} is the resistance of the channel transmission gate in the multiplexer shown in the block diagram. The offset is affected by the V\text{CC2} voltage and bus current. A higher V\text{CC2} voltage (V\text{CC} if V\text{CC2} is grounded) reduces R\text{MUX} leading to a lower offset. See the Typical Performance Characteristics plots for the variation of R\text{MUX} as a function of V\text{CC2} and temperature. When SCLOUT or SDAOUT is driven to a logic low voltage ≥ 200mV, SCLIN or SDAIN is regulated to a logic low voltage, as directed by equation 4 which uses SDA as an example:

\[
V_{\text{SDAIN}}(V) = V_{\text{SDAOUT}} + 45mV + 10\Omega \cdot \frac{V_{\text{DD,BUS}}}{R_{\text{BUS}}}.
\] (4)

The SCLOUT/SDAOUT to SCLIN/SDAIN offset is lower than the reverse case as the multiplexer transmission gate does not affect this offset. For driven logic low voltages <200mV, the above equations do not apply as the saturation voltage of the open collector output transistor results in a higher offset. However, the offset is guaranteed to be less than 400mV for a total bus pull-up current of 4mA under all conditions. See the Typical Performance Characteristics curves for the buffer offset voltages as a function of the driven logic low voltage and bus pull-up current.
APPLICATIONS INFORMATION

The high-to-low propagation delay arises due to both the finite response time of the buffers and their finite current sink capability. See the Typical Performance Characteristics curves for the propagation delay as a function of the bus capacitance.

Cascading LTC4314 devices and other LTC Bus Buffers

Multiple LTC4314s can be cascaded or the LTC4314 can be cascaded with other LTC bus buffers as required by the application. An example is shown for the clock pathway in Figure 5 where an LTC4314 is cascaded with another LTC4314 and some select LTC bus buffers. The data path is identical. When using such cascades, users should be aware of the additive logic low offset voltages \( V_{OS} \) when determining system noise margin. If the sum of the offsets (refer to equations 3 and 4 and to the data sheets of the corresponding bus buffers) plus the worst-case driven logic low voltage across the cascade exceeds the buffer turn-off voltage, signals will not be propagated across the cascade. Also the minimum rise time accelerator (RTA) turn-on voltage (wherever applicable) of each device in the cascade should also be greater than the maximum buffer turn-off voltage of all the devices in the cascade. This condition is required to prevent contention between one device’s buffer and another’s RTA.

Based on this requirement, the LTC4314 can be cascaded with the LTC4303 and LTC4307 if its RTA turn-on voltage is set to be 0.8V (ACC low). The LTC4314 can be cascaded with the LTC4301 and LTC4301L under all ACC settings as these devices do not have RTAs. The LTC4314 can be cascaded with the LTC4302, LTC4304, LTC4305 and LTC4306 if its RTAs are set to turn on at 0.8V (ACC low) or under all ACC settings if the RTAs on the other bus buffers are disabled. Finally two LTC4314s can be cascaded if their ACC pins are tied to the same state, HIGH, LOW or OPEN, or if the ACC pin of one LTC4314 is tied high and the other is left open.

Figure 5. Cascading an LTC4314 with Another LTC4314 and LTC Bus Buffers. Only the SCL Pathway Is Shown for Simplicity.
Paralleling LTC4314 Devices

The LTC4314s can be paralleled to perform higher order multiplexing. Figure 6 shows a 1:8 multiplexer with two LTC4314s.

Figure 6. Paralleling LTC4314 Devices to Realize an 1:8 Multiplexer
Figure 7 shows the use of the LTC4314 in a radial telecommunications application. Two shelf managers are wired to communicate with slave I²C devices for redundancy. Each shelf manager can have as many LTC4314s as required depending on the number of boards in the system and the desired radial/star configuration. The ENABLE pins of the LTC4314s inside only one shelf manager are asserted high at any time. For simplicity, in Figure 7 only the SDA pathway is shown. The SCL pathway is identical.

Figure 7. LTC4314s Configured for a Radially Connected Redundant Telecommunications Shelf Manager Application in a 6 x 4 Arrangement. The ENABLE Pins on Only One of the Shelf Managers Are High at Any Time. Only the SDA Path Is Shown for Simplicity
APPLICATIONS INFORMATION

Nested Addressing

The LTC4314 can provide nested addressing when its ENABLE pins are used as channel select bits. This is shown in Figure 8 where the master communicates with slave devices that have the same address by selectively enabling only one output channel at a time. Since slaves have the same address care must be taken that the master never enables channels 1 and 4 at the same time.

Stop Bit Generation and FAULT Clocking

If the output bus sticks low (SCLOUT or SDAOUT stuck low for at least 45ms) on one of the enabled channels and DISCEN is high, the LTC4314 attempts to unstick the bus by first breaking the connection between the input and output, asserting FAULT low and generating up to 16 clock pulses at 5.5kHz on the SCLOUT node common to the four channels. Should the stuck bus release high during this period, clock pulsing is stopped, a stop bit is generated and FAULT flag is cleared. In order for a connection to be established between the input and output, all ENABLES have to be taken low followed by an assertion of the ENABLES of the required channels. This process is illustrated in Figure 9 for the case where only channel 1 is active and SDAOUT1 starts out stuck low and then recovers. If DISCEN is tied low and a stuck low event occurs, the FAULT flag is driven low, but the connection between the input and output is not broken and clock generation is not done.

APPLICATIONS INFORMATION

Demultiplexer Function

Due to its bi-directional nature, the LTC4314 can be used as a demultiplexer. This is shown in Figure 10 where two channels are used to drive I²C data from the master side with redundancy to the slave side. In this application the SDAOUT/SCLOUT channels serve as the inputs while the SDAIN/SCLIN channel is the output. Redundancy on the master side provides protection against power supply failure. In Figure 10, if the 5V bus supply on channel 1 falls below 1.4V, channel 1 gets disabled as ENABLE1 is driven below its digital threshold. Simultaneously, the $V_{BE}$ of the pull-down device on ENABLE4 falls below 0.7V and it turns off. This causes ENABLE4 to be pulled up by R7 which in turn enables channel 4, causing control to be transferred to the backup I²C master device.

Hot-Swapping

Figure 11 shows the LTC4314 in a typical hot-swapping application where the LTC4314 is on the backplane and I/O cards plug into the downstream channels. The outputs must idle high and the corresponding output channel must be disabled before an I/O card can be plugged or unplugged from an output channel. Figure 11 also shows the use of a non-compliant I²C device with the LTC4314. The high noise margin of the LTC4314 supports logic low levels up to $0.3 \times V_{CC}$, allowing devices to drive greater than 0.4V logic low levels on the block and data lines.

Level Translating to Bus Voltages < 2.25V

The LTC4314 can be used for level translation to bus voltages below 2.25V if certain conditions are met. In order to perform this level translation, RTAs on the low voltage side need to be disabled in order to prevent an over drive of the low voltage bus. This can be accomplished by forcing ACC high or grounding $V_{CC2}$. If one of the output channels is pulled up to the low voltage bus supply, all other output channels need to be disabled when this channel is active, in order to prevent cross conduction between the output channels. Since the buffer turn-on and turn-off voltages are $0.3 \times V_{MIN}$, the minimum bus supply voltage is determined by equation 5:

$$V_{DD,BUS(MIN)} \geq \frac{0.3 \times V_{MIN}}{0.7} \tag{5}$$

in order to meet the $V_{IH} = 0.7 \times V_{DD,BUS}$ requirement and not impact the high side noise margin. Users willing to live with a lower logic high noise margin can level translate down to 1.5V. An example of voltage level translation from
3.3V to 1.8V is illustrated in Figure 12, where a 3.3V input voltage level is translated to a 1.8V output voltage level on channel 1. Tying $V_{CC}$ to 3.3V satisfies equation 5. Grounding $V_{CC2}$ disables the RTA on the low voltage channel. $V_{MIN}$ defaults to $V_{CC}$ under these conditions, making the buffer turn off voltage 0.99V. Channels 2-4 must be disabled when channel 1 is enabled. A similar voltage translation can also be performed going from a 3.3V bus supply on the output side to a 1.8V bus supply on the input side if ACC is tied high to disable the input RTA and if $V_{CC}$ and $V_{CC2}$ are tied to the output side bus supply.
