

INTRODUCTION

This application note describes the principle of operation of Dallas Semiconductor's line of direct-to-digital temperature sensors, and outlines a method of achieving high ($<0.05^{\circ}\text{C}$) resolution with these devices. An example C code listing is given for use with the DS1620.

DIRECT-TO-DIGITAL TEMPERATURE SENSOR PRINCIPLE OF OPERATION

The Dallas Direct-to-Digital Temperature Sensors measure temperature through the use of an onboard proprietary temperature measurement technique. A block diagram of the temperature measurement circuitry is shown in Figure 1.

Each temperature sensor measures temperature by counting the number of clock cycles that an oscillator with a low temperature coefficient goes through during a gate period determined by a high temperature coefficient oscillator. The counter is preset with a base count that corresponds to -55°C . If the counter reaches zero before the gate period is over, the temperature register, which is also preset to the -55°C value, is incremented, indicating that the temperature is higher than -55°C .

At the same time, the counter is then preset with a value determined by the slope accumulator circuitry. This circuitry is needed to compensate for the parabolic behavior of the oscillators over temperature. The counter is then clocked again until it reaches zero. If the gate period is still not finished, then this process repeats.

The slope accumulator is used to compensate for the nonlinear behavior of the oscillators over temperature, yielding a high resolution temperature measurement (0.5°C for almost all the products). This is done by changing the number of counts necessary for the counter to go through for each incremental degree in temperature. To obtain the desired resolution, therefore, both the value of the counter and the number of counts per degree C (the value of the slope accumulator) at a given temperature must be known.

TEMPERATURE MEASUREMENT CIRCUITRY Figure 1**INCREASING TEMPERATURE RESOLUTION**

Most of Dallas' direct-to-digital temperature sensors provide 0.5°C resolution directly. This is accomplished by the device determining whether to set or clear the least significant bit (LSB), based on the actual temperature. The device attempts to keep errors within ½ LSB, by quantizing different readings into the LSB step size. For example, a part which is ramping up in temperature from 25°C to +26°C, or down in temperature from –10°C to –11°C, would exhibit this behavior:

ACTUAL TEMPERATURE	SET/CLEAR LSB	DIRECT READING	ACTUAL TEMPERATURE	SET/CLEAR LSB	DIRECT READING
25	Clear	25	-10	Clear	-10
25.1	Clear	25	-10.1	Clear	-10
25.2	Clear	25	-10.2	Clear	-10
25.3	Set	25.5	-10.3	Set	-10.5
25.4	Set	25.5	-10.4	Set	-10.5
25.5	Set	25.5	-10.5	Set	-10.5
25.6	Set	25.5	-10.6	Set	-10.5
25.7	Set	25.5	-10.7	Set	-10.5
25.8	Clear	26	-10.8	Clear	-11
25.9	Clear	26	-10.9	Clear	-11
26	Clear	26	-11	Clear	-11

This example shows then that every reading is rounded up (in absolute value) by $\frac{1}{2}$ LSB. For most parts, this is 0.25°C. This is important to remember, since in doing calculations to achieve higher resolutions, this rounding factor must be taken into account.

With the exception of devices intended for battery management (DS2434 and DS2435), the temperature sensors can measure temperature over the range of -55°C to +125°C in 0.5°C increments. For Fahrenheit usage, a lookup table or conversion factor must be used.

Higher resolutions may be obtained by reading the temperature and truncating the least significant bit from the read value. From the example above, it should be apparent that this must be done on the raw, 9-bit number, in two's-complement arithmetic, in order for the correct reading to result. After the truncation, the number can then be converted into a signed integer. This value is referred to below as *temp_read*. The value left in the counter can then be read by issuing a special command protocol to the sensor. This value is the count remaining (*count_remain*) after the gate period has ceased. Reading the value of the slope accumulator (by using another command protocol or set of protocols, as outlined below) yields the number of counts per degree C (*count_per_degree*) at that temperature. Once these parameters are all known, the actual temperature can be calculated from the following equation:

$$TEMPERATURE = temp_read - \frac{1}{2}LSB + \frac{(count_per_degree - count_remain)}{count_per_degree}$$

A simple routine in C, called *CalHiResTemp*, is given in the listing of Figure 7.

PROCEDURES FOR READING COUNTER VALUES AND CALCULATING HIGH RESOLUTION TEMPERATURE READINGS

The following is a list of procedures for performing high resolution temperature readings from various digital thermometers. For all parts, conversions must be done in oneshot mode (if applicable). XXh refers to the protocol to send to the part; if two protocols are listed together (e.g., 84h A0h), both protocols should be sent in the given order, without resetting the part between protocols. A variable name XXX is designated as "named XXX."

NOTE:

The high-resolution temperature equation is slightly different for the DS1821 as compared to the DS1620, DS1623, DS1625, DS2434, and DS2435.

DS1620, DS1623, and DS1625:

1. Issue Start Convert protocol (EEh).
2. When conversion is finished, read 9-bit temperature value (AAh).
3. Truncate half-degree bit from reading.
4. Convert truncated value from 2's complement to signed integer (named *temp_read*).
5. Read 9-bit counter value (A0h; named *count_remain*).
6. Send undocumented Load Counter protocol (41h).
7. Read 9-bit counter value (A0h; named *count_per_degree*).

8. Calculate high-resolution temperature using the high resolution temperature equation given in the previous section. $\frac{1}{2}$ LSB = 0.25.

DS1621, DS1624, and DS1820:

The procedure to find the high resolution temperature parameters and the calculation to use are given in the respective product data sheets for these products. Note that since the DS1624 already provides a 13-bit number with 0.03125°C resolution, no further processing is possible to achieve any higher temperature resolution.

DS1821:

1. Issue Start Convert protocol (EEh).
2. When conversion is finished, read 8-bit temperature value (AAh).
3. Convert value from 2's complement to signed integer (named temp_read).
4. Read 9-bit counter value (A0h; named count_remain).
5. Send undocumented Load Counter protocol (41h).
6. Read 9-bit counter value (A0h; named count_per_degree).
7. Calculate high-resolution temperature using the high resolution temperature equation given in the previous section. Note that for the DS1821, $\frac{1}{2}$ LSB = 0.5.

DS2434 and DS2435:

1. Issue Start Convert protocol (D2h).
2. When conversion is finished, read 8-bit temperature value (B2h 61h).
3. Convert temperature value from 2's complement to signed integer (named temp_read).
4. Read 9-bit counter value (84h A0h; named count_remain).
5. Send undocumented Load Counter protocol (84h 41h).
6. Read 9-bit counter value (84h A0h; named count_per_degree).
7. Calculate high-resolution temperature using the high resolution temperature equation given in the previous section. $\frac{1}{2}$ LSB = 0.25.

EXAMPLE C CODE

The following example is a simple exerciser for the DS1620 from an IBM-PC compatible computer. It reads temperature and displays it in both the normal 0.5°C resolution and in high resolution. The DS1620 is inter-faced to the parallel port of the PC using the circuit shown in Figure 2, which is the schematic of the DS1620K demo kit.

The hardware for the DS1620K demo kit “steals” power from a parallel port using D1, D2, D3, and C3. Not all PC parallel ports are able to supply sufficient current to make this hardware work, so be advised that if this circuit does not work, try connecting a +5V power source to the +5V line in this circuit and try again. R1 and C1 serve to filter the CLK line and prevent negative under-shoots. Likewise, C2 helps prevent negative under-shoot on the DQ line.

The code is written in an attempt to make it easy to adapt to any of the digital temperature sensors. All that needs to be done to use it with other devices is to change the command header file to account for the protocols and resolution of the device being used, and change the files which manipulate the hardware interface to the device to account for either 1, 2 or 3-wire interfaces.

THREEWIR.H C CODE LISTING Figure 3

```
/* THREEWIR.H
```

This file defines the method for setting the 3-wire interface lines from an IBM-PC compatible computer. The interface is through the parallel port. The parallel port lines used are as follows:

/SELIN	pin 17	DQ
Data4	pin 5	CLK
Data3	pin 4	/RST
GND	pin 18	GND

The inportb, outportb, and delay functions are defined in most PC-based C compilers in dos.h

```
*/
```

```
#include <dos.h>
```

```
#define CLK_HI      p_data|= 0x08; outportb(p_addr,p_data); delay(1);
#define CLK_LOW    p_data&=~0x08; outportb(p_addr,p_data); delay(1);
#define RSTB_HI    p_data|= 0x04; outportb(p_addr,p_data); delay(1);
#define RSTB_LOW   p_data&=~0x04; outportb(p_addr,p_data); delay(1);
#define DQ_HI      outportb(p_addr+2,0x02); delay(1);
#define DQ_LOW     outportb(p_addr+2,0x0A); delay(1);
#define READ_BACK  -((inportb(p_addr+2) & 0x08) >> 3)+1
```

```
#define p_addr peek(0,0x0408) /* Finds the address of the parallel port */
```

```
char p_data = 0xFF;
```

DS3WIRE.C C CODE LISTING Figure 4

```

/* DS3wire.C
These routines handle a Dallas 3-wire interface. Methods of changing the individual
bit states in the hardware need to be defined in "threewir.h".
*/

#include "threewir.h"

/*
Bit level drivers, used in routines for handling the protocol and data interface to
a 3-wire device.
*/

/* Drives RSTB signal high (state=1) or low (state=0) */

void rb3w( int state )
{
    if (state==0) {RSTB_LOW;}
    else {RSTB_HI}
}

/* Drives CLK signal high (state=1) or low (state=0) */

void c3w( int state )
{
    if (state==0) {CLK_LOW}
    else {CLK_HI}
}

/* Drives DQ signal high (state=1) or low (state=0) */
void dq3w( int state )
{
    if (state==0) {DQ_LOW}
    else {DQ_HI}
}

/* Reads data back from port */

int rd_back()
{
    char i;
    i=READ_BACK;
    return( i );
}

```

```
/* Writes a 0 (w_bit=0) or a 1 (w_bit=1) to a three wire device. */
```

```
void write_bit( int w_bit )
{
    if ( w_bit == 0 ) dq3w( 0 );
    else dq3w( 1 );
    c3w( 0 );
    c3w( 1 );
    dq3w( 1 );
}
```

```
/* Reads a 0 (return 0) or a 1 (return 1) from a three wire device. */
```

```
int read_bit()
{
    int i;
```

```
    c3w( 0 );
    i=rd_back();
    c3w( 1 );
```

```
    return(i);
}
```

```
/*
Routines to read and write a Dallas 3-wire part. The three wire interface typically
requires that the part be sent an eight-bit protocol, followed by data. The
exception to this are the digital potentiometers, which use no protocols but send
only data. All transfers are LSB first.
```

If writing, the data must follow the protocol immediately, but there is no fixed number of bits that may be data.

If reading, the part must be written with an eight bit protocol; the DQ pin must then be changed to READ back data. As with writing, there is no fixed number of bits that may be data.

These routines are set up to handle an arbitrary data length UP TO the size of an int (which is typically 16 bits for most C compilers).

```
*/
```

```

/* write_part
Write a command and data to a 3-wire part. param is the integer value of the data to
be written after the write protocol. n_bits is the number of bits to transfer in
param.
*/

void write_part(int protocol, int param, int n_bits)
{
    int index, data;

    rb3w(1); /* Raise the /RST line */
    for (index = 0; index < 8; index++) /* protocol is 8 bits */
    {
        data = protocol >> index;
        data &= 0x01;
        write_bit(data);
    }
    for (index = 0; index < n_bits; index++) /* Write out data */
    {
        data = param >> index;
        data &= 0x01;
        write_bit(data);
    }
    rb3w(0); /* Drop /RST line */
}

/* read_part
Reads data from a 3-wire part. protocol is command to be written to the part, and
n_bits is number of bits to read after the protocol is sent. Returns int value of
reading.
*/

int read_part(int protocol, int n_bits)
{
    int index, data;
    int r_data = 0;

    rb3w(1); /* Raise the /RST line */
    for (index = 0; index < 8; index++) /* protocol is 8 bits */
    {
        data = protocol >> index;
        data &= 0x01;
        write_bit(data);
    }

    for (index = 0; index < n_bits; index++) /* Read in data */
    {
        r_data |= read_bit() << index;
    }
    rb3w(0);
    return(r_data);
}
